OFER STRICHMAN, TECHNION, ISRAEL

ALEXANDER IVRII, IBM-HAIFA, ISRAEL

# CLAUSE REPLICATION

---

- Recall **clause replication** [S'01,S'04] for BMC.
  - Enhances learning with extra clauses, not related to the current path.
  - Based on the regular structure of BMC formulas.
- Our contributions here:
  - Identify this property in many other problem domains
  - **Theory**: Show how it extends **dynamic symmetry handling** [DBB'17,TD'19]
  - **Practice**: Experiments with various learning / forgetting strategies.

# CLAUSE REPLICATION IN BMC [S'01,S'04]

- BMC (of safety properties):  $\text{BMC}_k \equiv I(S_0) \wedge \bigwedge_{i=0..k-1} T(S_i, S_{i+1}) \wedge \neg P(S_k)$
- At the CNF level  $T(S_i, S_{i+1})$  is the same for each  $i$ , up to renaming.
- This can be exploited for learning additional clauses:

Gliding symmetry:

# Clause replication in BMC [S'01,S'04]

---

Maintain additional clause header data:

1. Is this clause 'replicable' ?
2. (min,max) cycle used for deriving this clause:

When learning a new clause  $c$  from antecedents  $S$  (i.e.,  $S \vdash c$ ):

If all of  $S$  clauses are marked:

1. Mark  $c$ .
2. Record (min,max) cycle indices in  $S$ .
3. Learn  $c^i$  for  $i \in -min..(k - max)$ .

# EXAMPLE

$$s = (-x_2 \ y_5), (x_2 \ y_5 \ z_3 \ w_4)$$

$$(min, max) = (2, 5), \ k = 6$$

y						
z						
w						
	0	1	2	3	4	5

$$c = (y_5 \ z_3 \ w_4)$$

Going right

y						
z						
w						
	0	1	2	3	4	5

$$c^1 = (y_6 \ z_4 \ w_5)$$

Going left

y						
z						
w						
	0	1	2	3	4	5

$$c^{-1} = (y_4 \ z_2 \ w_3)$$

$$c^{-2} = (y_3 \ z_1 \ w_2)$$

# THE SAME PRINCIPLE APPLIES TO MANY OTHER FORMULAS

---

- In previous works:
  - Bounded model checking [S'01,S'04]
  - Planning with neural networks [SDNS'20]
- Here we apply it to various problems that drew attention in recent years:
  - Van-Der Waerden numbers
  - Pythagorean triples
  - The 'Sweep' problem
  - The 'Anti-bandwidth' problem
  - Cardinality constraints

# EXAMPLE 1: VAN-DER WAERDEN NUMBERS

- The van der Waerden number  $W(k)$  is the smallest integer  $n$  such that every 2-coloring of  $1..n$  has a monochromatic arithmetic progression of length  $k$ .
- E.g., a bad coloring for  $n = 9, k = 3$

- It can be shown that  $W(3) = 9$ .
- We have a witness for  $W(3) > 8$

# EXAMPLE 1: VAN-DER WAERDEN NUMBERS

---

- For a sequence length  $n$ , define  $n$  variables
  - $x_i$  - for  $1 \leq i \leq n$ , location  $i$  is with color '1'.
- Suppose  $k = 3, n = 10$ . Then:
  - No 3 consecutive literals with gap 1 are all '0':  $(1\ 2\ 3)\ (2\ 3\ 4)\ (3\ 4\ 5)\ \dots\ (8\ 9\ 10)$
  - No 3 consecutive literals with gap 2 are all '0':  $(1\ 3\ 5)\ (2\ 4\ 6)\ (3\ 5\ 7)\ \dots\ (6\ 8\ 10)$
  - No 3 consecutive literals with gap 3 are all '0':  $(1\ 4\ 7)\ (2\ 5\ 8)\ (3\ 6\ 9)\ (4\ 7\ 10)$
  - No 3 consecutive literals with gap 4 are all '0':  $(1\ 5\ 9)\ (2\ 6\ 10)$
- + same for all color '1': negate all literals, e.g.,  
 $(-1, -2, -3)\ (-2, -3, -4)\ (-3, -4, -5)\ \dots\ (-8, -9, -10)$

## EXAMPLE 2: PYTHAGOREAN TRIPLES

---

- Triples  $(a, b, c)$  such that  $a^2 + b^2 = c^2$
- Q: for a given  $n \in \mathbb{N}$ , can  $1..N$  be separated to two sets, such that no set contains a Pythagorean triple ?
- Example CNF for  $n = 17$ 

(3 4 5)	(-3 -4 -5)
(5 12 13)	(-5 -12 -13)
(6 8 10)	(-6 -8 -10)
(9 12 15)	(-9 -12 -15)
(8 15 17)	(-8 -15 -17)

## EXAMPLE 2: PYTHAGOREAN TRIPLES

- Example CNF for  $n = 17$ 

3 4 5	-3 -4 -5
5 12 13	-5 -12 -13
6 8 10	-6 -8 -10
9 12 15	-9 -12 -15
8 15 17	-8 -15 -17
- Symmetry emanates from factoring triples

- Going left: divide  $c$  by a common divisor of the antecedents
- Going right: multiply  $c$  by a factor  $f$ , as long as  $f \cdot \max \leq n$  ( $\max$  = maximal literal in  $c$ 's antecedents).

# A THEORETICAL FRAMEWORK

---

- Static (full) symmetry –
  - **Static symmetry breaking** [Shatter, BreakID] – Statically adding Symmetry-Breaking constraints.
  - **Dynamic symmetry handling** [e.g., SEL (DBB'17)] – Given a learned clause  $c$ , adding **extra** clauses (“**eclauses**”) based on symmetry data.
- This talk – we find eclauses regardless of static symmetry.
  - The theory is based on isomorphic subgraphs

# THE CNF INCIDENCE GRAPH

---

- The **colored literals incidence graph** of  $(-a, b, c)^{C_1}$   $(a, -b)^{C_2}$ :

- Opposite literals are connected
- A clause node is connected to its literals
- Literals have one color, clauses another.

# STATIC SYMMETRY IN CNF, BY EXAMPLE

$\varphi$ :

$C_1$ :	$(\neg a, b, c)$
$C_2$ :	$(a, \neg b, \neg c)$
$C_3$ :	$(\neg b, c)$

Syntactic equivalence  
up to clause/literals  
reordering

Find a **Boolean-consistent** map  $\sigma$  between the labels, such that  $\sigma(\varphi) \equiv \varphi$ .

Example:  $\sigma: (a, \neg a)(b, \neg c)(C_1, C_2)$

$\sigma(\varphi)$ :

	$(a, \neg c, \neg b)$
	$(\neg a, c, b)$
	$(c, \neg b)$

# STATIC SYMMETRY IN CNF, BY EXAMPLE

$$\varphi: \begin{array}{l} C_1: (-a, b, c) \\ C_2: (a, -b, -c) \\ C_3: (-b, c) \end{array}$$

$\alpha$ :    |        0        0        |        0        |

Find a **Boolean-consistent** map  $\sigma$  between the labels, such that  $\sigma(\varphi) \equiv \varphi$ .

Example:  $\sigma: (a, -a)(b, -c)(C_1, C_2)$

Hence, if  $\alpha \models \varphi$  then  $\sigma(\alpha) \models \varphi$

$\sigma(\alpha)$ :    |        0        0        |        0        |

# STATIC SYMMETRY BREAKING

---

- So  $\sigma$  in our example has the property that  $\forall \alpha. \alpha \models \varphi \Rightarrow \sigma(\alpha) \models \varphi$ .
- We only need one representative to maintain satisfiability.
- **Shatter/BreakID** find such mappings, and add **symmetry-breaking constraints**.
  - How ? See Crawford et al [CGLR96].

# DYNAMIC SYMMETRY HANDLING\*

---

Suppose we learned a new clause  $C_4$ .

Hence  $\varphi \vdash_{res} C_4$

$\Rightarrow \sigma(\varphi) \vdash_{res} \sigma(C_4)$

$\Rightarrow \varphi \vdash_{res} \sigma(C_4)$

Conclusion: we can learn also  $\sigma(C_4)$

Note that:

1. This **does not break the symmetry**; all solutions remain.
2. The map  $\sigma$  was built statically, according to symmetries in  $\varphi$ .

\* Used by SEL [BDB'17], SLS [BNOS'10], SP [BBDDM'12]

# “ALMOST SYMMETRIES” [CBMSI 4,...]

---

- Suppose we have  $\varphi \equiv \varphi_1 \cup \varphi_2$ 
  - $\varphi_1$  prevents symmetry.
  - But there is still a mapping  $\sigma$  such that  $\sigma(\varphi_2) \equiv \varphi_2$
- If we learn a clause  $c$  from  $\varphi_2$ , we can also add the eclause  $\sigma(c)$ .

Our work: a weaker condition for eclauses.

	Symmetry	Almost Symmetry
Usage	Static, dynamic	Dynamic
Formula	$\varphi$	$\varphi_1 \cup \varphi_2$
Requires	$\sigma(\varphi) \equiv \varphi$	$\sigma(\varphi_2) \equiv \varphi_2$

# THE SUBGRAPH INDUCED BY A RESOLUTION PROCESS

Consider the resolution process (root clauses in green):

$$\begin{array}{c} \hline (-a, b) \quad (a, c) \\ \hline (b, c) \quad (a, -b, d) \\ \hline (a, c, d) \end{array}$$

The **subgraph induced by the resolution process** is a union of

- The subgraphs corresponding to the root clauses
- The edges of the resolved variables

# THE SUBGRAPH INDUCED BY A RESOLUTION PROCESS

Consider the resolution process (root clauses in green):

$$\begin{array}{c} \hline (-a, b) \quad (a, c) \\ \hline (b, c) \quad (a, -b, d) \\ \hline (a, c, d) \end{array}$$

Any subgraph isomorphic to this one, corresponds to a legal resolution.

# THE SUBGRAPH INDUCED BY A RESOLUTION PROCESS

Consider the resolution process (root clauses in green):

$$\frac{\frac{(-a, b) \quad (a, c)}{(b, c) \quad (a, -b, d)}}{(a, c, d)}$$

Isomorphic subgraphs  $\Leftrightarrow$  isomorphic subformulas.

Q: How can this fact be used?

A: look for formulas in which this property can be detected statically

# THE SUBGRAPH INDUCED BY A RESOLUTION PROCESS

Consider the resolution process (root clauses in green):

$$\frac{\frac{(-a, b) \quad (a, c)}{(b, c) \quad (a, -b, d)}}{(a, c, d)}$$

Isomorphic subgraphs  $\Leftrightarrow$  isomorphic subformulas.

Q: How can this fact be used?

A: look for formulas in which this property can be detected statically

# THE SUBGRAPH INDUCED BY A RESOLUTION PROCESS

Q: How can this fact be used?

A: look for formulas in which this property can be detected statically

- Let  $\varphi \equiv \varphi_1 \cup \varphi_2 \cup \varphi_3$  and let  $\sigma$  be a partial map such that  $\sigma(\varphi_2) \equiv \varphi_3$
- Typically  $\varphi_2 \cap \varphi_3 \neq \emptyset$ .

	Symmetry	Almost Symmetry	This work
Usage	Static, dynamic	Dynamic	Dynamic
Formula	$\varphi$	$\varphi_1 \cup \varphi_2$	$\varphi_1 \cup \varphi_2 \cup \varphi_3$
Requires	$\sigma(\varphi) \equiv \varphi$	$\sigma(\varphi_2) \equiv \varphi_2$	$\sigma(\varphi_2) \equiv \varphi_3$

# THE SUBGRAPH INDUCED BY A RESOLUTION PROCESS

Q: How can this fact be used?

A: look for formulas in which this property can be detected statically

- Let  $\varphi \equiv \varphi_1 \cup \varphi_2 \cup \varphi_3$  and let  $\sigma$  be a partial map such that  $\sigma(\varphi_2) \equiv \varphi_3$
- Typically  $\varphi_2 \cap \varphi_3 \neq \emptyset$ .
- Examples:

Problem	Map type	$\varphi_1$	$\varphi_2$	$\varphi_3$
BMC	$+j$	$I(0), P(k)$	$c \in T(i, i+1)$	$c^j \in T(i+j, i+j+1)$
Van-Der Waerden	$+j$		$c \in \varphi$	$c^j \in \varphi$
Pyth. triples	$*j$		$c \in \varphi$	$c^{*j} \in \varphi$

# THE E-CLAUSES: WHAT KIND OF CLAUSES ARE THESE ?

---

- They are loosely related to the search
  - On the one hand, they refer to a **different set of variables** than the current focus
  - On the other, they build **a clause structure (proof?) which is symmetric** to the learned one.
    - In that sense, they are not 'arbitrary' implied clauses.
- Does adding them as additional learned clauses improve performance?

# ADDITION / DELETION STRATEGY FOR E-CLAUSES

---

- Addition:
  - During search / restart: **restart**
  - Maximal size: **20**
  - Maximal (partial\*) LBD: **6**
    - Measured with respect to the current trail
    - It does not necessarily include a full assignment of the e-clause.
  - Maximal # of non-false literals: **3**
- Deletion:
  - Initial score: **0.8x**
  - Category (core / Tier-2 / Local): **Local**
  - Deletion ratio (% of local clauses removed during 'reduceDB'): **66%**

# RESULTS

---

Symmetry	Replication	Time (par-2)	Conflicts	e-clauses
static	✓	111.2	1,079,719	30568
		149.8	2,110,472	0
		190.4	2,112,666	0
dynamic	✓	198.5	1,963,104	50618
dynamic		233.2	2,477,840	6,729

30 non-trivial instances, 16 unsat.  
Includes eclause filtering.

# CONCLUSIONS

---

- Future work:
  - Better adaptation of solvers to this extra information
  - “Symbolic clauses” – generate eclauses lazily.
